### (54) Method for calibrating a thermal printer

(57) A method for calibrating a thermal printer, having a thermal head incorporating a plurality of energisable heating elements, comprises the step of supplying to the thermal printer a thermographic material (m), a plurality of printer data  $P_i$  each intended to be recorded as a pixel having a density  $D_i$ , and default reference values for printing parameters comprising a value  $P_{ref}$  for a reference printing power; and the step of printing a calibration pattern for the plurality of printer data  $P_i$ , the calibration pattern comprising a multiple step density wedge such that a whole range of a relation  $D_i(P_i)$  be-

tween the printer data  $P_i$  and the density  $D_i$  is covered. Further steps comprise measuring a density  $D_{exp,i}$  for each patch of the density wedge of the calibration pattern in relation to the plurality of printer data  $P_i$  and storing a first set  $S1=(P_{ref}, P_i, D_{exp,i})$  in a first memory (M1); calculating, for a desired density  $D_{want,j}$ , a corresponding value  $P_{refnew,j}$  for the reference printing power and storing a second set  $S2=(D_{want,j}, P_{refnew,j})$  in a second memory M2 calculating, for the desired density  $D_{want,j}$ , for each printer data  $P_i$  a corresponding density  $D_i$  and storing a third set  $S3=(D_{want,j}, P_{refnew,j}, P_i, D_i)$  in a third memory M3.

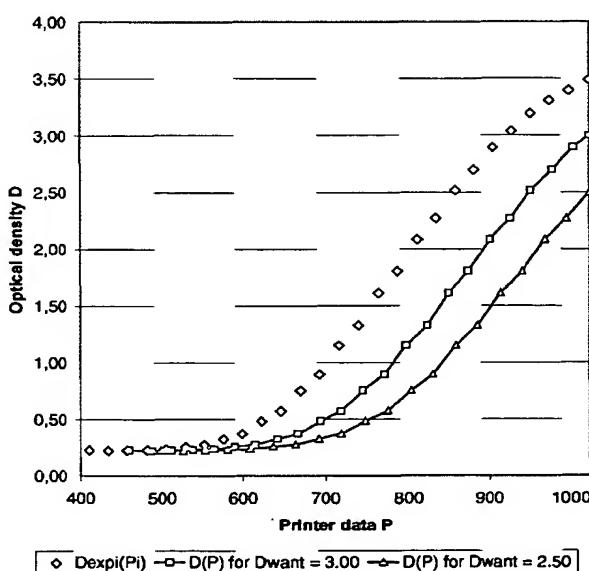

FIG. 2

**Description****FIELD OF THE INVENTION**

**[0001]** The present invention relates to a method for applying thermal energy to a recording medium, using a thermal head having energisable heating elements which are individually addressable. More specifically the invention concerns a method for calibrating a continuous tone thermal printer. In particular, the recording medium is a thermographic material, and the method for thermal printing relates to thermography.

**BACKGROUND OF THE INVENTION**

**[0002]** Thermal imaging or thermography is a recording process wherein images are generated by the use of imagewise modulated thermal energy. Thermography is concerned with materials which are not photosensitive, but are sensitive to heat or thermosensitive and wherein imagewise applied heat is sufficient to bring about a visible change in a thermosensitive imaging material, by a chemical or a physical process which changes the optical density.

**[0003]** Most of the direct thermographic recording materials are of the chemical type. On heating to a certain conversion temperature, an irreversible chemical reaction takes place and a coloured image is produced.

**[0004]** In direct thermal printing, the heating of the thermographic recording material may be originating from image signals which are converted to electric pulses and then through a driver circuit selectively transferred to a thermal print head. The thermal print head consists of microscopic heat resistor elements, which convert the electrical energy into heat via the Joule effect. The electric pulses thus converted into thermal signals manifest themselves as heat transferred to the surface of the thermographic material, e.g. paper, wherein the chemical reaction resulting in colour development takes place. This principle is described in "Handbook of Imaging Materials" (edited by Arthur S. Diamond - Diamond Research Corporation - Ventura, California, printed by Marcel Dekker, Inc. 270 Madison Avenue, New York, ed. 1991, p. 498-499).

**[0005]** A particular interesting direct thermal imaging element uses an organic silver salt in combination with a reducing agent. An image can be obtained with such a material because under influence of heat the silver salt is developed to metallic silver.

**[0006]** A thermal printer varies the printing energy to control the density of the thermal print. The objective is to print predictable densities with minimum increments to produce a nearly continuous grey scale over the desired density range. Typically, control is a two stage process.

**[0007]** A traditional technique for calibrating a thermal printer is as follows.

First, a first calibration page is printed with a limit setting

to produce the desired maximum density and a full range of print settings. The next step is to determine whether this is the desired limit setting by visually inspecting the printed page. The normal objective is to find

5 the minimum exposure required to print the full range of desired densities. The lower the limit setting, the more nearly continuous the grey scale in the printed film. The process of printing and adjusting the maximum limit setting is repeated until a desired limit setting is determined.

**[0008]** Next, a second calibration page is printed with the limit system setting selected and with a subset of print system settings which cover the full range of print settings. The resulting densities of the printed page are

15 then measured and a print setting to density table created for the full range of print settings. An output lookup table that can be used to set exposure to produce the desired density for any digital image value is created using the print setting to density table. Thereafter the thermal printer prints pages with this output lookup table to produce the desired densities while the same maximum exposure is appropriate.

20 However, if maximum exposure is changed the calibration process must be repeated.

**[0009]** A problem which arises with this calibration technique is that calibration data is specific to a particular limit control setting. If that setting needs to be changed the entire process of successive prints to find the desired limit control setting for maximum density and 30 calibration must be repeated. Also, if different users want different maximum densities each requires separate calibration. Such repeated calibrations is inefficient, costly and non-productive.

**OBJECTS OF THE INVENTION**

**[0010]** It is an object of the present invention to provide an improved calibration method for recording an image on a thermal imaging element by means of a thermal head having energisable heating elements.

40 It is a further object of the invention that the calibration method has the ability to produce a single calibration page and to derive from that single page sufficient information to produce calibrated prints over a wide range of densities.

**[0011]** Other objects and advantages of the present invention will become clear from the description and the drawings.

**SUMMARY OF THE INVENTION**

**[0012]** The above mentioned objects are realised by a calibration method having the characteristics defined in the independent claims. Specific features for preferred embodiments of the invention are set out in the dependent claims.

**[0013]** Further advantages and embodiments of the present invention will become apparent from the following

ing description.

#### BRIEF DESCRIPTION OF THE DRAWINGS

**[0014]** The invention will be described hereinafter with reference to the accompanying drawings, which are not intended to restrict the scope of the present invention. Herein,

Figure 1 shows a preferred embodiment of a calibration method according to the present invention, and Figure 2 is a diagram showing experimentally measured densities and finally obtained densities in relation to printer data.

#### DETAILED DESCRIPTION OF THE INVENTION

**[0015]** For sake of good understanding it is mentioned that in this specification often an index "i" is used in relation to certain data (e.g. printer data  $P_i$ , a density  $D_i$ , thermal head data  $TH_i$ , rescaled thermal head data  $TH'_i$ , etc), whereas an index "j" is used to indicate a user-related variable (e.g.  $Prefnew_j$ , a desired density  $Dwant_j$ , ...). Of course, in some situations, a combination of both indexes is applicable (e.g. a density  $D_{ji}$ ). In order to keep the reading of the specification as easy as possible, often such combined index "ji" is simplified to a single index "i", although people skilled in the art may very well understand that implicitly a combined index "ji" is understood.

**[0016]** First, attention is focused on the drawings, wherein figure 1 shows a preferred embodiment of a calibration method according to the present invention, and wherein figure 2 is a diagram showing experimentally measured densities and finally obtained densities in relation to printer data. As to Fig.1, a so called "slicing" and a so called "duty cycle" (in this drawing indicated with "DC") are explained in full depth e.g. in EPA-01000003.2 (in the name of Agfa-Gevaert); an example of a "user taste" (in this drawing indicated by the abbreviation "U") is explained e.g. in EP-0536822 (in the name of Agfa-Gevaert), a type of a "compensation" (in this drawing indicated with "TPH—Control - compensations") and the meaning of a "voltage supplied to the thermal head" (in this drawing indicated with "V<sub>TH</sub>") are explained in full depth e.g. in EP-0714780 (in the name of Agfa-Gevaert). For sake of conciseness, no redundant descriptions are repeated for said technical terms.

**[0017]** In the present specification the term "reference printing power Pref" means the power dissipated under reference conditions comprising  $V_{TH}$ ,  $R_{ref}$  and  $D_{ref}$ , and more particularly the time-averaged power dissipated during a 100% time slice.

**[0018]** According to the present invention and in reference to figures 1 and 2, a method for calibrating a thermal printer comprising a thermal head incorporating a plurality of energisable heating elements, comprises the steps of:

- 5 - supplying to said thermal printer a thermographic material  $m$ , a plurality of printer data  $P_i$  each intended to be recorded as a pixel having a density  $D_{ji}$ , and default reference values for printing parameters  $\Pi$  comprising a value  $Pref$  for a reference printing power;
- 10 - printing a calibration pattern for said plurality of printer data  $P_i$ , said calibration pattern comprising a multiple step density wedge such that a whole range of a relation  $D_{ji}(P_i)$  between said printer data  $P_i$  and said density  $D_{ji}$  is covered;
- 15 - measuring a density  $Dexp_i$  (see Fig. 2) for each patch of said density wedge of said calibration pattern in relation to said plurality of printer data  $P_i$  and storing a first set  $S1 = (Pref, P_i, Dexp_i)$  in a first memory  $M1$ ;
- 20 - calculating, for a desired density  $Dwant_j$  (see Fig. 2 illustrating  $Dwant_j$  being 2.50 or being 3.00), a corresponding value  $Prefnew_j$  for said reference printing power and storing a second set  $S2 = (Dwant_j, Prefnew_j)$  in a second memory  $M2$ ;

25 calculating, for said desired density  $Dwant_j$ , for each printer data  $P_i$  a corresponding density  $D_{ji}$  and storing a third set  $S3 = (Dwant_j, Prefnew_j, P_i, D_{ji})$  in a third memory  $M3$ .

**[0019]** Taking into account the remarks about the indexes "i", "j" and "ji", all further embodiments will be indicated with a single index "i" instead of a combined index "ji".

30 As a comparative example, the just mentioned embodiment now is also rephrased with single indexes "i".

**[0020]** Thus, in a first preferred embodiment of a method for calibrating a thermal printer comprising a thermal head incorporating a plurality of energisable heating elements, said method comprising the steps of:

- 40 - supplying to said thermal printer a thermographic material  $m$ , a plurality of printer data  $P_i$  each intended to be recorded as a pixel having a density  $D_i$ , and default reference values for printing parameters  $\Pi$  comprising a value  $Pref$  for a reference printing power;
- 45 - printing a calibration pattern for said plurality of printer data  $P_i$ , said calibration pattern comprising a multiple step density wedge such that a whole range of a relation  $D_i(P_i)$  between said printer data  $P_i$  and said density  $D_i$  is covered;
- 50 - measuring a density  $Dexp_i$  for each patch of said density wedge of said calibration pattern in relation to said plurality of printer data  $P_i$  and storing a first set  $S1 = (Pref, P_i, Dexp_i)$  in a first memory  $M1$ ;
- 55 - calculating, for a desired density  $Dwant_j$ , a corresponding value  $Prefnew_j$  for said reference printing power and storing a second set  $S2 = (Dwant_j, Prefnew_j)$  in a second memory  $M2$ ;
- calculating, for said desired density  $Dwant_j$ , for each printer data  $P_i$  a corresponding density  $D_i$  and

storing a third set  $S3 = (Dwant_j, Prefnew_j, P_j, D_i)$  in a third memory M3.

**[0021]** In another preferred embodiment according to the present invention, a method for calibrating a thermal printer comprising a thermal head incorporating a plurality of energisable heating elements, said method comprising the steps of:

- supplying a thermographic material m, a plurality of printer data  $P_i$  to be recorded, and default reference values for printing parameters  $\Pi$  comprising a value  $Pref$  for a reference printing power;
- printing a calibration pattern for said plurality of printer data  $P_i$ , said calibration pattern comprising a multiple step density wedge such that a whole range of a relation  $Di(P_i)$  between said printer data  $P_i$  and said density  $Di$  is covered;
- measuring a density  $Dexp_i$  for each patch of said density wedge of said calibration pattern in relation to said plurality of printer data  $P_i$  and storing a first set  $S1 = (Pref, P_i, Dexp_i)$  in a first memory M1;
- transforming said printer data  $P_i$  to thermal head data  $TH_i$  (see Fig. 1) according to a transformation H applying  $H(P_i) \geq TH_o$  and  $H(P_m) \geq H(P_n)$  for  $P_m > P_n$ , wherein  $TH_o$  is a minimal value of thermal head data to be addressed, and wherein  $P_m$  and  $P_n$  are arbitrary values of said printer data  $P_i$ ;
- finding a value  $THDwant_j$  for said thermal head data  $TH_i$  corresponding with said desired density  $Dwant_j$ ;
- calculating, at said desired density  $Dwant_j$ , a corresponding value  $Prefnew_j$  for said reference printing power taking into account said  $Pref$ , said  $THDwant_j$  and  $THmax$ , wherein  $THmax$  is a maximal value of thermal head data that can be addressed, and storing a fourth set  $S4 = (Dwant_j, Prefnew_j)$  in a fourth memory M4;
- calculating, for said desired density  $Dwant_j$ , for each available printer data  $P_i$  a corresponding density  $Di$  and storing a sixth set  $S6 = (Dwant_j, Prefnew_j, P_j, D_i)$  into a sixth memory M6.

**[0022]** It may be indicated that in practice, the contents of memory M2 often equals to the contents of memory M4. The same applies to the contents of memories M3 and M6.

**[0023]** In another preferred embodiment according to the present invention, a method for calibrating a thermal printer comprising a thermal head incorporating a plurality of energisable heating elements, said method comprises the steps of:

- supplying a thermographic material m, a plurality of printer data  $P_i$  to be recorded, and default reference values for printing parameters  $\Pi$  comprising a value  $Pref$  for a reference printing power;
- printing a calibration pattern for said plurality of printer data  $P_i$ , said calibration pattern comprising

a multiple step density wedge such that a whole range of a relation  $Di(P_i)$  between said printer data  $P_i$  and said density  $Di$  is covered;

- measuring a density  $Dexp_i$  for each patch of said density wedge of said calibration pattern in relation to said plurality of printer data  $P_i$  and storing a first set  $S1 = (Pref, P_i, Dexp_i)$  in a first memory M1;
- transforming said printer data  $P_i$  to thermal head data  $TH_i$  according to a transformation H applying  $H(P_i) \geq TH_o$  and  $H(P_m) \geq H(P_n)$  for  $P_m > P_n$ , wherein  $TH_o$  is a minimal value of thermal head data to be addressed, and wherein  $P_m$  and  $P_n$  are arbitrary values of said printer data  $P_i$ ;
- finding a value  $THDwant_j$  for said thermal head data  $TH_i$  corresponding with said desired density  $Dwant_j$ ;
- calculating, at said desired density  $Dwant_j$ , a corresponding value  $Prefnew_j$  for said reference printing power taking into account said  $Pref$ , said  $THDwant_j$  and  $THmax$ , wherein  $THmax$  is a maximal value of thermal head data that can be addressed, and storing a fourth set  $S4 = (Dwant_j, Prefnew_j)$  in a fourth memory M4;
- converting said thermal head data  $TH_i$  into rescaled thermal head data  $TH'_i$  taking into account  $TH_i$ , said  $THDwant_j$  and said  $THmax$ ;
- recalculating said rescaled thermal head data  $TH'_i$  into rescaled printer data  $P'_i$  according to a transformation  $H'$  characterised by  $H'(TH') \geq 0$  and  $H'(TH'_m) \geq H'(TH'_n)$  for  $TH'_m > TH'_n$ ;
- storing a relation  $S5$  between said rescaled printer data  $P'_i$  and said measured density  $Dexp_i$  (from S1) into a fifth memory M5;
- deriving from said relation  $S5$  (in memory M5), for said desired density  $Dwant_j$ , for each available printer data  $P_i$  a corresponding density  $Di$  and storing a sixth set  $S6 = (Dwant_j, Prefnew_j, P_j, D_i)$  into a sixth memory M6.

**[0024]** In further preferred embodiment according to the present invention, said steps of supplying, printing a calibration pattern, and measuring a density  $Dexp_i$  for each patch of said density wedge, are replaced by capturing a new value for a desired density  $Dwant_j$ .

**[0025]** In further preferred embodiment according to the present invention, said step of printing a calibration pattern is preceded by the steps

- supplying to said thermal printer a plurality of image data  $d$  to be recorded on said thermographic material m;
- first converting said image data  $d$  into density data  $Di$  according to a desired relation  $U$  between each of said image data  $d$  and a corresponding density  $Di$ ;
- second converting said density data  $Di$  into printer data  $P_i$  by using the  $(P, D_i)$  information in a previous set  $S3$  corresponding to said  $Dwant_j$ ;
- storing thus (twice) converted image data  $d$  as a set

S7 = (d, P<sub>i</sub>) into a seventh memory M7.

[0026] In a further preferred embodiment according to the present invention, said steps of first converting said image data d and of second converting said density data D<sub>i</sub> are carried out by a transforming according to  $T = S^{-1} \circ U$  (meaning that operation first U has to be carried out, and thereafter operation S<sup>-1</sup>; see also Fig. 1)

[0027] In a still further preferred embodiment according to the present invention, said default reference values for printing parameters  $\Pi$  are selected from the group of a reference value for a resistance value R<sub>ref</sub> of a heating element (e.g. R<sub>ref</sub> = 3000  $\Omega$ ), a reference value D<sub>Cref</sub> for a duty cycle (e.g. D<sub>Cref</sub> = 70%), and a reference value T<sub>ref</sub> for a base-temperature of a heating element (e.g. T<sub>ref</sub> = 25 °C).

[0028] In a still further preferred embodiment, said calculating, a corresponding value Prefnew<sub>j</sub> is carried out according to

$$\text{Prefnew}_j = \text{Pref.} \cdot \frac{TH_{D_{\text{want}},j}}{TH_{\text{max}}}.$$

[0029] In a still further preferred embodiment according to the present invention, said converting said thermal head data TH<sub>i</sub> into rescaled thermal head data TH<sub>i</sub>' is carried out according to

$$TH_i' = TH_i \cdot \frac{TH_{\text{max}}}{TH_{D_{\text{want}},j}}.$$

[0030] In a still further preferred embodiment according to the present invention, said transforming said printer data P<sub>i</sub> to thermal head data TH<sub>i</sub> is carried out according to

$$TH_i = TH_0 + P_i \cdot \frac{(2^N - 1 - TH_0)}{2^N - 1}$$

wherein N is a bitdepth (representing a number of bits per value) of said thermal head data TH<sub>i</sub>.

[0031] In a still further preferred embodiment according to the present invention, said recalculating said rescaled thermal head data TH<sub>i</sub>' into rescaled printer data P<sub>i</sub>' is carried out according to

$$P_i' = (TH_i' - TH_0) \cdot \frac{2^N - 1}{2^N - 1 - TH_0}.$$

[0032] In another preferred embodiment according to the present invention, a method further comprises the step of searching two consecutive values of thermal head data TH<sub>k</sub> and TH<sub>i</sub> which correspond with densities D<sub>k</sub> and D<sub>i</sub> wherein between a desired density Dwant<sub>j</sub> is

enclosed.

[0033] In another preferred embodiment, said step of transforming said printer data P<sub>i</sub> to thermal head data TH<sub>i</sub> applies according to following equation:

$$TH_i = TH_0 + P_i \cdot \frac{(2^N - 1 - TH_0)}{2^M - 1}$$

10 wherein N is a bitdepth (representing a number of bits) of said thermal head data TH, and M is a bitdepth (representing a number of bits) of said printer data P<sub>i</sub>, and wherein M is different from N, preferably N > M.

In a highly preferred embodiment, e.g. M = 10 or 12, and N = 13.

[0034] In another preferred embodiment, a method for thermal recording by means of a thermal head incorporating a plurality of energisable heating elements H<sub>n</sub> and using a calibration method according to anyone of the preceding disclosures.

[0035] In still another preferred embodiment, said thermographic material comprises on a support a thermosensitive layer incorporating an organic silver salt and a reducing agent contained in said thermosensitive layer and/or in another optional layer.

[0036] From another point of view, an apparatus for thermal recording an image on a thermographic material using a method as described hereabove.

[0037] In a still further preferred embodiment, said 30 output values Dh<sub>k</sub>, Dh<sub>kcm</sub> and Dh<sub>kcm</sub> relate to values of an optical density and/or to values of a pixel size to be reproduced on said thermographic material m.

[0038] An experiment to test the performance of a calibration method according to the present invention was 35 carried out on a Drystar3000 thermal printer (commercially available from Agfa-Gevaert). The results of the most important steps of the calibration procedure are listed in table 1 (in appendix).

[0039] A 27 step calibration wedge was printed at a 40 reference printing power Pref of 75.6 mW. The 27 printer data values P<sub>1</sub>, P<sub>2</sub>, ..., P<sub>27</sub> lay between 411 and 1023. The 27 corresponding experimental density values lay between 0.23 and 3.49.

[0040] The 27 printer data values P<sub>1</sub>, P<sub>2</sub>, ..., P<sub>27</sub> 45 were transformed to 27 thermal head data values TH<sub>1</sub>, TH<sub>2</sub>, ..., TH<sub>27</sub>.

[0041] In the described example, the above listed experimental results from the single calibration page were further used to obtain all the necessary information to 50 guarantee high quality printouts at two different values of Dwant, e.g. Dwant = 2.50 and Dwant = 3.00.

[0042] THD<sub>want</sub> and Prefnew were calculated. For Dwant = 2.50, THD<sub>want</sub> = 6950 and consequently Prefnew = 64.1 mW. For Dwant = 3.00 on the other hand, THD<sub>want</sub> = 7436 and Prefnew = 68.16 mW.

[0043] For each Dwant-value, the rescaled P-values (indicated by the symbol P') were calculated and the output lookup table that is used during printing to set the

appropriate energy to produce the desired density for any digital image value was created.

**[0044]** Finally, the quality of the calibration was tested by printing at said two values of  $D_{want}$ , i.e. 2.50 and 3.00, another test wedge, in particular a 33 step test wedge, and by comparing the experimental densities with the desired densities. Over the full density range, the difference between two corresponding densities was never larger than 2%. This result clearly demonstrates that the objects of the present invention are realised.

**[0045]** Thermal imaging according to the present invention can be used for production of both transparencies and reflection-type prints. In the hard copy field, thermographic recording materials based on an opaque (e.g. white) base are used, whereas in the medical diagnostic field monochrome (e.g. black) images on a transparent base find wide application, since such prints can conveniently be viewed by means of a light box.

**[0046]** The method of the present invention is applicable for a wide variety of printing techniques.

**[0047]** In "Direct thermal printing", the method may be directed towards representing an image of a human body obtained during medical imaging and to a printing of medical image picture data received from a medical imaging device, e.g. a medical image camera.

**[0048]** Another application of the present invention comprises hardcopy printing for so-called non-destructive Testing (NDT), based on e.g. radiographic or on ultrasonic systems. Exemplary purposes of NDT comprise inspection or quality control of materials, welded joints or assemblies; development of manufacturing processes; experimenting in research; etc.

**[0049]** In another preferred embodiment of the present invention, the image data may be graphical image picture data received e.g. from a computerised publishing system. Further, a method according to the present invention also may be applied in graphic plotters, in chart recorders, in computer printers, etc.

**[0050]** In a still further preferred embodiment, said densities (as e.g.  $D_{ji}$ ,  $D_{expj}$  and  $D_{wantj}$ ) relate to values of an optical density and/or to values of a pixel size to be reproduced on said thermographic material m.

**[0051]** Further, it is important to indicate that for people skilled in the art, a so-called heating element may comprise e.g. a resistive heating element, an inductive heating element, a pyrotechnic heating element, or a high frequency heating element.

**[0052]** Having described preferred embodiments of the current invention, it will now be apparent to those skilled in the art that numerous modifications can be made therein without departing from the scope of the invention as defined in the appending claims.

## Claims

### 1. A method for calibrating a thermal print r compris-

ing a thermal head incorporating a plurality of energisable heating elements, said method comprising the steps of:

- 5 - supplying to said thermal printer a thermographic material m, a plurality of printer data  $P_i$  each intended to be recorded as a pixel having a density  $D_i$ , and default reference values for printing parameters  $\Pi$  comprising a value  $Pref$  for a reference printing power;
- 10 - printing a calibration pattern for said plurality of printer data  $P_i$ , said calibration pattern comprising a multiple step density wedge such that a whole range of a relation  $D_i(P_i)$  between said printer data  $P_i$  and said density  $D_i$  is covered;
- 15 - measuring a density  $D_{expi}$  for each patch of said density wedge of said calibration pattern in relation to said plurality of printer data  $P_i$  and storing a first set  $S1 = (Pref, P_i, D_{expi})$  in a first memory  $M1$ ;
- 20 - calculating, for a desired density  $D_{wanti}$ , a corresponding value  $Prefnew_i$  for said reference printing power and storing a second set  $S2 = (D_{wanti}, Prefnew_i)$  in a second memory  $M2$ ;
- 25 - calculating, for said desired density  $D_{wanti}$ , for each printer data  $P_i$  a corresponding density  $D_i$  and storing a third set  $S3 = (D_{wanti}, Prefnew_i, P_i, D_i)$  in a third memory  $M3$ .

30 2. A method for calibrating a thermal printer comprising a thermal head incorporating a plurality of energisable heating elements, said method comprising the steps of:

- 35 - supplying a thermographic material m, a plurality of printer data  $P_i$  to be recorded, and default reference values for printing parameters  $\Pi$  comprising a value  $Pref$  for a reference printing power;
- 40 - printing a calibration pattern for said plurality of printer data  $P_i$ , said calibration pattern comprising a multiple step density wedge such that a whole range of a relation  $D_i(P_i)$  between said printer data  $P_i$  and said density  $D_i$  is covered;
- 45 - measuring a density  $D_{expi}$  for each patch of said density wedge of said calibration pattern in relation to said plurality of printer data  $P_i$  and storing a first set  $S1 = (Pref, P_i, D_{expi})$  in a first memory  $M1$ ;
- 50 - transforming said printer data  $P_i$  to thermal head data  $TH_i$  according to a transformation  $H$  applying  $H(P_i) \geq TH_o$  and  $H(P_m) \geq H(P_n)$  for  $P_m > P_n$ , wherein  $TH_o$  is a minimal value of thermal head data to be addressed, and wherein  $P_m$  and  $P_n$  are arbitrary values of said printer data  $P_i$ ;
- 55 - finding a value  $THD_{wanti}$  for said thermal head data  $TH_i$  corresponding with said desired den-

sity  $D_{want,j}$ ;

- calculating, at said desired density  $D_{want,j}$ , a corresponding value  $P_{prefnew,j}$  for said reference printing power taking into account said  $P_{pref}$ , said  $THD_{want,j}$  and  $TH_{max}$ , wherein  $TH_{max}$  is a maximal value of thermal head data that can be addressed, and storing a fourth set  $S4 = (D_{want,j}, P_{prefnew,j})$  in a fourth memory  $M4$ ;
- calculating, for said desired density  $D_{want,j}$ , for each available printer data  $P_i$  a corresponding density  $D_i$  and storing a sixth set  $S6 = (D_{want,j}, P_{prefnew,j}, P_i, D_i)$  into a sixth memory  $M6$ .

3. A method for calibrating a thermal printer comprising a thermal head incorporating a plurality of energisable heating elements, said method comprising the steps of:

- supplying a thermographic material  $m$ , a plurality of printer data  $P_i$  to be recorded, and default reference values for printing parameters  $\Pi$  comprising a value  $P_{pref}$  for a reference printing power;
- printing a calibration pattern for said plurality of printer data  $P_i$ , said calibration pattern comprising a multiple step density wedge such that a whole range of a relation  $D_i(P_i)$  between said printer data  $P_i$  and said density  $D_i$  is covered;
- measuring a density  $D_{exp,i}$  for each patch of said density wedge of said calibration pattern in relation to said plurality of printer data  $P_i$  and storing a first set  $S1 = (P_{pref}, P_i, D_{exp,i})$  in a first memory  $M1$ ;
- transforming said printer data  $P_i$  to thermal head data  $TH_i$  according to a transformation  $H$  applying  $H(P_i) \geq TH_o$  and  $H(P_m) \geq H(P_n)$  for  $P_m > P_n$ , wherein  $TH_o$  is a minimal value of thermal head data to be addressed, and wherein  $P_m$  and  $P_n$  are arbitrary values of said printer data  $P_i$ ;
- finding a value  $THD_{want,j}$  for said thermal head data  $TH_i$  corresponding with said desired density  $D_{want,j}$ ;
- calculating, at said desired density  $D_{want,j}$ , a corresponding value  $P_{prefnew,j}$  for said reference printing power taking into account said  $P_{pref}$ , said  $THD_{want,j}$  and  $TH_{max}$ , wherein  $TH_{max}$  is a maximal value of thermal head data that can be addressed, and storing a fourth set  $S4 = (D_{want,j}, P_{prefnew,j})$  in a fourth memory  $M4$ ;
- converting said thermal head data  $TH_i$  into rescaled thermal head data  $TH'_i$  taking into account  $TH_i$ , said  $THD_{want,j}$  and said  $TH_{max}$ ;
- recalculating said rescaled thermal head data  $TH'_i$  into rescaled printer data  $P'_i$  according to a transformation  $H'$  **charact. rised by**  $H' (TH')$

5  $\geq 0$  and  $H' (TH'_m) \geq H' (TH'_n)$  for  $TH'_m > TH'_n$  ; storing a relation  $S5$  between said rescaled printer data  $P'_i$  and said measured density  $D_{exp,i}$  (from  $S1$ ) into a fifth memory  $M5$ ;

10 - deriving from said relation  $S5$  (in memory  $M5$ ), for said desired density  $D_{want,j}$ , for each available printer data  $P_i$  a corresponding density  $D_i$  and storing a sixth set  $S6 = (D_{want,j}, P_{prefnew,j}, P_i, D_i)$  into a sixth memory  $M6$ .

15 4. A method according to anyone of the claims 1-3, wherein said steps of supplying, printing a calibration pattern, and measuring a density  $D_{exp,i}$  for each patch of said density wedge, are replaced by capturing a new value for a desired density  $D_{want,j}$ .

20 5. A method according to anyone of the claims 1-4, wherein said step of printing a calibration pattern is preceded by the steps of

- supplying to said thermal printer a plurality of image data  $d$  to be recorded on said thermographic material  $m$ ;
- first converting said image data  $d$  into density data  $D_i$  according to a desired relation  $U$  between each of said image data  $d$  and a corresponding density  $D_i$ ;
- second converting said density data  $D_i$  into printer data  $P_i$  by using the  $(P, D_i)$  information in a previous set  $S3_{prev}$  corresponding to said  $D_{want,j}$ ;
- storing thus (twice) converted image data  $d$  as a set  $S7 = (d, P_i)$  into a seventh memory  $M7$ .

25 35 6. A method according to claim 5, wherein said steps of first converting said image data  $d$  and of second converting said density data  $D_i$  are carried out by a transforming according to  $T = S^{-1} \circ U$ .

40 45 7. A method according to anyone of the claims 1-3 wherein said default reference values for printing parameters  $\Pi$  are selected from the group of a reference value for a resistance value  $R_{ref}$  of a heating element, a reference value  $D_{Cref}$  for a duty cycle, and a reference value  $T_{ref}$  for a temperature of a heating element.

50 55 8. A method according to claim 2 or 3, wherein said calculating, a corresponding value  $P_{prefnew,j}$  is carried out according to

$$Prefnew_j = Pref \cdot \frac{TH_{D_{want,j}}}{TH_{max}}$$

55 9. A method according to claim 2 or 3, wherein said converting said thermal head data  $TH_i$  into rescaled thermal head data  $TH'_i$  is carried out according to

$$TH_i' = TH_i \cdot \frac{TH_{max}}{TH_{Dwant_j}}.$$

10. A method according to claim 2 or 3, wherein said transforming said printer data  $P_i$  to thermal head data  $TH_i$  is carried out according to 5

$$TH_i = TH_0 + P_i \cdot \frac{(2^N - 1 - TH_0)}{2^N - 1} \quad 10$$

wherein N is a bitdepth (representing a number of bits pro value) of said thermal head data  $TH_i$ . 15

11. A method according to claim 2 or 3, wherein said recalculating said rescaled thermal head data  $TH_i'$  into rescaled printer data  $P_i'$  is carried out according to 20

$$P_i' = (TH_i' - TH_0) \cdot \frac{2^N - 1}{2^N - 1 - TH_0}.$$

12. A method according to claim 2 or 3, further comprising the step of searching two consecutive values of thermal head data  $TH_k$  and  $TH_l$  which correspond with densities  $D_k$  and  $D_l$  wherein between a desired density  $D_{want_j}$  is enclosed. 25

30

13. A method according to claim 2, wherein said step of transforming said printer data  $P_i$  to thermal head data  $TH_i$  applies according to following equation:

$$TH_i = TH_0 + P_i \cdot \frac{(2^N - 1 - TH_0)}{2^M - 1} \quad 35$$

wherein N is a bitdepth (representing a number of bits) of said thermal head data  $TH_i$ , and M is a bitdepth (representing a number of bits) of said printer data  $P_i$ , and wherein M is different from N. 40

14. A method for thermal recording by means of a thermal head incorporating a plurality of energisable heating elements  $H_n$  and using a calibration method according to anyone of the preceding claims. 45

15. A method according to anyone of the preceding claims, wherein said thermographic material comprises on a support a thermosensitive layer incorporating an organic silver salt and a reducing agent contained in said thermosensitive layer and/or in another optional layer. 50

55

16. An apparatus for thermal recording an image on a thermographic material using a method according to anyone of the preceding claims.

ANNEX TO THE EUROPEAN SEARCH REPORT  
ON EUROPEAN PATENT APPLICATION NO.

EP 01 00 0107

This annex lists the patent family members relating to the patent documents cited in the above-mentioned European search report. The members are as contained in the European Patent Office EDP file on. The European Patent Office is in no way liable for these particulars which are merely given for the purpose of information.
